Search & Navigation

Our industry leading product makes searching and consuming information more intuitive for users.

Cascading Searches

This feature enables users to easily start a new search stemming from information and insights gleaned during an initial search. Likewise, users can refine their existing search results to perform a more specific secondary search.

For example, if a user is reviewing and updating employee personal data, their initial search results set will likely show each employee's date of birth, passport number, address, nationality, and job role. By selecting specific entities of interest, such as the passport number and the date of birth for a subset of employees, the user can trigger a secondary search to reveal a separate set of related insights.

Cherry-picking definitive entities not only reduces manual inputting, but seamlessly automates new queries for faster searches. This is particularly useful when users are pursuing different lines of investigation or collating information according to related entities. This continuous cycle of searches supports regulatory or compliance activities.

Timeline Visualisation

This feature enables users to visualise a chronological series of events based on specific structured, crawled, and enriched information. Connecting the dots, it clearly highlights patterns found in diverse data sets to surface previously hidden insights.

For example, users can easily visualise timeline events for a customer or supplier, such as when an invoice status transitioned from 'in progress' to 'paid'. Or users can see when an employee moved from one company to another, altered job role, or changed their home address. Showcasing affiliations with other organisations can reveal potential conflicts of interest or suspicious activity, supporting additional investigatory decisions and activities.

Search & Navigation

Our industry leading product makes searching and consuming information more intuitive for users.

Histogram Visualisation

When users are searching for information to support a task at hand, they may well be presented with a vast number of search results. Users can now plot these search results across a specific timeframe, whether that's the previous five years or just six months, to reveal new visual insights.

For example, if a large volume of data records or files are created, changed, or updated at specific time points, the histogram will clearly show spikes in activity, adding context to search results for a more perceptive user experience. When reviewing customer complaints to improve customer service, this feature makes it easier to spot trends and peak patterns in large volumes of data. It can also be used to track spikes in faulty product reports, supporting decisions to improve the design and manufacturing life cycle. Similarly, users can more easily observe outliers, indicating suspicious or non-compliant activities, and take further investigative action.

Map View

This feature intelligently plots information with an address or geo-point directly onto a geographical map. First, the Aiiimi Insight Engine enriches addresses or geo-points captured in data (such as database records and documents) stored on your corporate systems. Second, it transfers this information onto a map view, so users can visualise their search findings in context to support decision making.

This is particularly useful for utilities and manufacturers because it enables users to easily locate all sites and assets on just one map. Similarly, suppliers can easily locate their customers at a glance. Or during investigations, users can clearly see the locations of organisations and individuals.

Search & Navigation

Our industry leading product makes searching and consuming information more intuitive for users.

Alerting on a Saved Search

When a user has performed a search, they can now opt to save that search and set up a dedicated alert. When new results directly match that saved search, the user will receive an automated email notification. This not only reduces the amount of time spent re-running searches on the Aiimi Insight Engine, but also proactively delivers all new and updated information and insights directly to the user's inbox every day or week, as required, for added convenience.

Network Diagram Improvements – Default Sub Model Linking

When two diverse data records are linked within search, this feature displays a description of the underlying connection. Users can now clearly see why the information is interlinked and what they have in common. This enables administrators to seamlessly configure data models to correctly render information presented within the application.

For example, users searching for an individual will also see links to other people working for the same company, even if the company data is different (e.g., 'Company Ltd' vs 'Company Limited'). By showing relationships between data records more transparently and explicitly than might be the case in underlying source systems, this feature reveals new insights to users.

Search & Navigation

Our industry leading product makes searching and consuming information more intuitive for users.

Network Diagram Improvements – Upper Limit Configuration (Performance and Scalability)

When expanding the network diagram feature to view connections stitching multiple nodes of data together, there may be some instances when search performance could be compromised. This is particularly the case when large volumes of data need to be populated.

To support a more sustainable and consistent search performance for all users interacting with the network diagram feature, this new configuration setting enables administrators to select an upper limit for the number of connections exposed to users accessing the network diagram at any one time.

Adding Visualisations to a Collection

When viewing details for a specific search result using a visualisation feature, such as the network diagram or timeline visualisation, users can choose to save the visualisation to a collection as a PDF, independently of the wider search results.

This feature is useful during regulatory or compliance processing when users are gathering and compiling data as evidence for disclosure.

Our industry leading product makes searching and consuming information more intuitive for users.

Changes to Default Settings for Search Settings

When users log in to the Aiimi Insight Engine for the very first time, they are asked to rank the relevancy of all sources available. On subsequent searches, insights from their more highly ranked sources will be automatically boosted to the top of their search results.

Previously, all sources were defaulted to a medium setting. Unless administrators pre-set the source rankings, users had no knowledge of any source rank settings being universally applied by the administrator. Now, all sources in search settings are automatically defaulted to any pre-configured ranking set by the administrator.

For example, administrators could rank SharePoint as high and Dropbox as low based on the organisation's universal frequency of use. If a user wants to override this universal ranking with their own boosting preferences, they can now do so.

Essential Maintenance

**Constant maintenance to future
proof our core product.**

Add Support for Azure AD SSO (SAML 2.0) Authentication to Search

SAML 2.0 Authentication enables the Aiimi Insight Engine to authenticate user identities against industry standard SAML 2.0 service providers, in addition to existing options for LDAP, Windows, and ADFS.

When a user logs in to the Aiimi Insight Engine, they are now redirected to the SAML 2.0 portal to input their credentials. This benefits organisations that adopt multi-factor authentication as part of their security protocols and organisations that prefer this primary method to ADFS or other providers.

.Net V6 Upgrade

.NET v5 is only supported until May 2022, so we have carried out essential maintenance to move Aiimi Insight Engine onto the latest version, .NET V6 (released in November 2021). This maintains integrity of the platform.

Thumbnail Management – Creation Time Range Configuration Setting (Administrative Change)

When files are indexed and enriched, administrators can now specify a time range for thumbnail generation. This is calculated using the modified date on each file. For example, administrators can specify that thumbnails are only generated for files modified during the previous 6 or 12 months. When the modified date is less recent than the time range set, the thumbnail for that file will automatically be removed.

Deleting thumbnails for less frequently used data, while maintaining thumbnails for more active data sets of higher value, alleviates storage demands and associated costs.

Thumbnail Management – Marking and Reprocessing (Administrative Change)

Within the Aiimi Insight Engine, administrators can now audit and validate all indexed and enriched files with and without a thumbnail. For indexed files without a thumbnail, this feature automatically triggers reprocessing to accurately generate a thumbnail as needed.

Users can schedule daily, weekly, or monthly reprocessing to continually check and update changes to indexed and enriched files, ensuring thumbnails are accurately generated as needed. Likewise, when files are deleted from source systems, this ensures the thumbnail is also removed.

Automating the management and maintenance of thumbnails minimises the number of search results omitting thumbnails and optimises the overall user experience.

Visualisation PDF Storage Control Hub Configuration (Administrative Change)

When a user chooses to save a network diagram and/or timeline visualisation to a collection as a PDF, it first needs to be saved and stored in a pre-configured location. This feature allows administrators to configure and specify that storage location.

Known Issues

Manage

Exporting as a PDF on Linux doesn't work.

Search Results

No fallback icons shown for data-related search results.

Privileged Access Mode

When changing the privilege access setting in a data record and clicking the back button, the new privilege isn't persisted.

KPI Chart

x-axis dates are incorrectly shown.
